

What This EA Does

StraddleReplica is an automated gold trading EA for MT5. It places buy-stop orders above the current price and sell-stop orders below it. The aim is to join a strong move in either direction.

about 92%

estimated behavioral similarity

In one sentence

It builds a ladder of pending orders around gold, manages opened trades with protective stops, closes the trading basket, then starts a fresh ladder.

THE BASIC SHAPE

60

pending orders at startup

30 + 30

buy stops above and sell stops below

XAUUSD

designed for gold on a hedging account

WHAT THE EVIDENCE SUPPORTS

- **46 of 46 observed grid deployments matched** the expected order sequence, spacing, and overall shape.
- The combined evidence supports **approximately 92%** overall behavioral similarity to the target EA.
- The stop pattern is estimated at about **95-97% confidence**, but it was reconstructed from trade history rather than source code.

Important: this is not proven 100% identical

The original source code was not available. Broker prices, spread, slippage, order timing, and hidden target-EA rules can change real trades. The similarity figure is an engineering estimate, not a promise.

How the Grid Works

Think of the grid as a price ladder. Buy orders wait above the starting price. Sell orders wait below it. A pending order becomes a live trade only when price reaches that level.

LOT SIZE GROUPS

Levels 1-10

0.01 lot
Closest to the starting price.

Levels 11-20

0.06 lot
Middle part of the ladder.

Levels 21-30

0.15 lot
Farthest and largest orders.

THE DISTANCE BETWEEN LEVELS

The spacing changes with the gold price. When gold is higher, the distance becomes slightly wider. In the observed target pattern, the step was close to the starting gold price divided by 3,000.

Pending does not mean open

At startup there may be 60 waiting orders, but they are not all live positions. They open only as price travels through the ladder.

How Trades Are Managed

The EA treats each filled level as part of one larger trading basket. It mainly protects winners by changing stop-loss levels instead of using a separate take-profit on every trade.

1. A pending order opens

When gold touches a buy-stop or sell-stop level, that waiting order becomes an active market position.

2. First protective stop

After price moves far enough in the trade's favor, the EA adds or moves a stop to reduce the risk on that position.

3. Second profit lock

If the move continues, the stop is moved again so more of the open profit is protected if price turns back.

4. The level can be rearmed

After a stopped trade, the EA can place that level again after about one second, as long as the order price is valid.

Basket close and restart

The EA watches the group of trades as one basket. Near the observed target of about **\$30**, it cancels remaining pending orders, closes positions, and prepares a new grid. The observed restart is usually about **two seconds** later.

Spread and slippage can make the final account result different from the target amount.

What is known and what is estimated

The two-stage stop behavior is strongly supported by the trade history, with an estimated 95-97% match. The exact hidden calculation inside the original EA cannot be proven without its source code.

One Simple Trading Cycle

A cycle starts when the EA creates a fresh grid and ends when that basket is closed. The EA then builds the next grid around a new starting price.

EXAMPLE IN SIMPLE TERMS

- 1 Build the ladder.** The EA places 30 buy stops above gold and 30 sell stops below it.
- 2 Gold starts rising.** The closest buy stops open one after another as price climbs.
- 3 Protect the winners.** The EA moves stops on trades that have gained enough.
- 4 Reuse stopped levels.** A stopped level may be placed again after the one-second gate.
- 5 Finish the basket.** The EA cancels waiting orders and closes remaining positions.
- 6 Start again.** A fresh grid is normally created about two seconds later.

The usual winning pattern

Many trades can close for small stop-locked gains while the move continues through the grid.

The important losing pattern

A reversal or basket reset can close leftover trades together. One larger basket loss can follow many small wins.

Key point: a high percentage of winning trades does not remove the risk of a large losing basket.

Real-Account Installation

These steps explain a manual MT5 setup. Menu names can vary slightly between brokers. The real preset allows live trading, so check every setting before you press OK.

1 Install the EA

In MT5 choose File > Open Data Folder. Put the supplied .ex5 file in MQL5/Experts, then refresh Navigator or restart MT5.

2 Open the gold chart

Use your broker's gold symbol. It may be XAUUSD, XAUUSDm, GOLD, or another broker-specific name.

3 Check the account type

The account must support hedging, meaning buy and sell positions can exist at the same time.

4 Check broker capacity

The broker must allow at least 60 pending orders plus any open positions created during the cycle.

5 Attach and load

Drag the EA onto the gold chart. In Inputs choose Load and select LATEST_30_REAL_EXACT.set.

6 Start and watch

Enable Algo Trading, press OK, and confirm that the first grid appears without order errors in the Experts or Journal tab.

Live-account settings in the real preset

RequireDemoAccount=false means the EA is allowed to run on a real account.

SafetyEnabled=false means the optional safety layer is disabled. Do not mistake this setting for account protection.

Strongly recommended before live money

Run the same broker, symbol, and preset on demo first. Then use only capital you can afford to lose and confirm that margin remains comfortable when several larger outer levels open.

Risks and Operating Checklist

This EA can build exposure quickly. Real-account results depend on the broker and the market, not only on the EA logic.

Fast exposure growth

Outer grid orders are 0.15 lot each. Several fills can increase margin use quickly.

Gold can jump

News, gaps, and fast moves can skip expected prices or trigger many levels in a short time.

Execution can differ

Spread, slippage, latency, rejected orders, and stop levels vary between brokers.

Basket losses can be large

Many small wins can be followed by one larger close of leftover positions.

Broker limits matter

Order-count limits, minimum distance rules, and symbol settings can prevent an exact grid.

Extra safety is off

The real preset uses `SafetyEnabled=false`. Have your own loss and shutdown plan.

BEFORE STARTING

- Correct gold symbol and chart.
- Hedging account confirmed.
- At least 60 pending orders allowed.
- Preset name and inputs checked.
- Enough free margin and a manual stop plan.

KEEP THESE RECORDS

- Experts and Journal logs.
- Account history and broker statements.
- Screenshots of unusual cycles.
- Spread, rejection, and slippage notes.
- Any broker symbol-rule changes.

Final truth about the match

The EA is estimated at **approximately 92%** behavioral similarity. It is not proven 100% identical, and that percentage does not guarantee the same trades or profit on a real account. Monitor every live cycle.
